

# **ISO TC184/SC4/ WG11 N 137**

**Date: December 9, 2000**

**Supersedes SC4/ WG11 N 076**

## **PRODUCT DATA REPRESENTATION AND EXCHANGE**

### **Part: 35**

**Title:** Conformance Testing Methodology and Framework:  
Abstract Test Methods for SDAI Implementations

#### **Purpose of this document as it relates to the target document is:**

- Primary Content      Current Status: working  
 Issue Discussion  
 Alternate Proposal  
 Partial Content

#### **ABSTRACT:**

This part of ISO 10303 describes test methods for use in the conformance testing of software systems implementing, in one or more language binding, a level of functionality (implementation class) as specified in ISO 10303-22.

#### **COMMENTS TO THE READER:**

Since WG11N076 the majority of needed test cases (130) has been added. The SDAI\_test\_operation\_schema has been improved and completed. Further work and checking of the SDAI\_test\_case\_schema is needed. Annex C is added to show how the test-cases may be realized by an SDAI implementation. Nothing is done so far on formatting this document.

#### **KEYWORDS:**

## **Foreword**

The ISO (International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has a right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

Draft International Standards adopted by technical committees are circulated to the member bodies for voting. Publication as an International Standard requires approval by at least 75% of the member bodies casting a vote.

International Standard ISO 10303-22 is being prepared by Technical Committee ISO/TC 184, *Industrial automation systems and integration*, Subcommittee SC4, *Industrial data and global manufacturing languages*.

ISO 10303 consists of the following parts under the general title *Industrial automation systems and integration - Product data representation and exchange*:

- Part 1, Overview and fundamental principles;
- .... (to be added )

Should further parts be published, they will follow the same numbering pattern.

The reader may obtain information on the other Parts of ISO 10303 from the ISO Central Secretariat.

Annex A forms an integral part of this part of ISO 10303. Annex B is for information only.

## **Introduction**

ISO 10303 is an International Standard for the computer-interpretable representation and exchange of product data. The objective is to provide a neutral mechanism capable of describing product data throughout the life cycle of a product, independent from any particular system. The nature of this description makes it suitable not only for neutral file exchange, but also as a basis for implementing and sharing product databases and archiving.

ISO 10303 is organized as a series of parts, each published separately. The parts of this International Standard fall into one of the following series: descriptive methods, integrated resources, application protocols, abstract test suites, implementation methods, and conformance testing. The series are described in ISO 10303-1. This part of ISO 10303 is a member of the conformance testing series.

This part of ISO 10303 specifies test methods used in the conformance testing of software systems implementing the Standard data access interface (SDAI) for one or more language bindings in one of the classes of implementation specified in ISO 10303-22.

# **Industrial automation systems and integration - Product data representation and exchange - Part 35: Conformance Testing Methodology and Framework: Abstract Test Methods for SDAI implementations**

## **1 Scope**

This part of ISO 10303 presents the abstract test methods and requirements for conformance testing of an implementation of a language binding of the SDAI. Since the SDAI is specified independently of any programming language, the abstract test methods presented in this part will be applicable to all language bindings specified for the SDAI. The abstract test methods specified herein will also address early and late bindings to application protocol schemata as well as the various classes of implementation detailed in ISO 10303-22.

The following are within the scope of this document:

- abstract test methods for software systems that implement the SDAI;
- conformance tests for all SDAI operations specified in ISO 10303-22;
- the specification, in a manner that is independent of any binding language<sup>1</sup>, of algorithms and approaches for the testing of various SDAI operations;
- the specification and documentation of abstract test cases

The following are outside the scope of this document:

- the development of test data and/or test programs for specific language bindings;
- the specification of test methods, algorithms, or programs for the conformance testing of applications that interact with SDAI implementations;
- implementation policy for a conformance test system that realizes the test methods specified in this part of ISO 10303.

## **2 Normative references**

The following standards contain provisions which, through reference in this text, constitute provisions of this part of ISO 10303. At the time of publication, the editions indicated were valid. All standards are subject to revision, and parties to agreements based on this part of ISO 10303 are encouraged to investigate the possibility of applying the most recent editions of the standards indicated below. Members of IEC and ISO maintain registers of currently valid International Standards.

ISO 10303-1

*Industrial automation systems and integration - Product data representation*

---

<sup>1</sup>Binding-specific functions need to be tested as well. Although this part of ISO 10303 is language-independent, the issue of testing such functions needs to be addressed.

## **3 Definitions**

### **3.1 Terms defined in ISO 10303-1**

This part of ISO 10303 makes use of the following terms defined in ISO 10303-1:

- abstract test suite;
- application protocol;
- conformance class;
- implementation method;
- Protocol Implementation Conformance Statement;
- PICS proforma;

### 3.2 Terms defined in ISO 10303-22

This part of ISO 10303 makes use of the following terms defined in ISO 10303-22:

- application schema;
- implementation class;
- domain equivalence;
- language binding;
- repository;
- schema instance;
- SDAI-model;
- session;
- validation;

### 3.3 Terms defined in ISO 10303-31

This part of ISO 10303 makes use of the following terms defined in ISO 10303-31:

- abstract test case;
- abstract test method;
- conformance;
- conformance log;
- conformance report;
- conformance testing;
- executable test case;
- FAIL (verdict);
- implementation under test;
- INCONCLUSIVE (verdict);
- PASS (verdict);
- Protocol Implementation eXtra Information for Testing;
- PIXIT proforma;

- test campaign;
- test case error;
- test laboratory;
- test report;
- (test) verdict;
- verdict criteria;

### **3.4 Abbreviations**

The following abbreviations are used in this part of ISO 10303:

IUT	Implementation Under Test
PICS	Protocol Implementation Conformance Statement
PIXIT	Protocol Implementation eXtra Information for Testing
SDAI	Standard Data Access Interface

## **4 Requirements and overview**

A conformance test system for SDAI implementations will possess the capability of testing a SDAI implementation (the IUT) for its claimed behavior against requirements specified in ISO 10303-22 and companion parts depending on the programming language the IUT supports.

This part of ISO 10303 describes abstract test methods that conformance test systems would implement in order to test SDAI implementations. General principles and an overall framework for conformance testing are provided in ISO 10303-31. Requirements on test laboratories are defined in ISO 10303-32. The methods for preparing, controlling, observing and analyzing implementations during testing are defined in this part of ISO 10303.

### **4.1 SDAI Testing requirements**

These test methods described in this part of ISO 10303 will address the following testing requirements:

- An SDAI implementation may be early bound, late bound, or both. Test methods specified in this part of ISO 10303 address all such implementations.
- An SDAI implementation must obey the state model described in ISO 10303-22. The test methods specified in this part ensure this is tested.
- ISO 10303-22 is written independent of any programming language. The test methods specified for SDAI will therefore be generic.
- ISO 10303-22 specifies various levels of functionality that an SDAI implementation can support.

The test methods specified herein will facilitate the testing of implementations at these various levels or implementation classes.

- SDAI operations provide means for data manipulation and transactions. Testing these operations will provide assurance of their correctness and whether they had the desired effect on the persistent storage. These operations include create, delete, modify, validate and various manipulation operations that act on schema instances, SDAI-models, and instances of application schema entities.
- In situations of error, SDAI operations return error codes. Testing will encompass all reasonable error situations for an operation to ensure that appropriate error codes are returned.
- Dictionary information operations provide subtype/supertype and complex entity information, interface information, and domain equivalence information. In the case of late bound applications, the dictionary is *closed*<sup>2</sup>, and will be tested implicitly.
- Environment and session operations provide the capability for changing the state of the SDAI session. Conformance testing will ascertain that only the permitted transitions take place and that only permitted operations for a state are allowed.
- The testing of error handling requires checking the returned error value against the actual error condition which triggered that return value.
- Aggregate operations play important roles in SDAI implementations, facilitating the successful completion of other complex operations or sequences of operations.
- Verdicts must be issued for all test cases executed.
- Test logs and reports that accurately capture the results of all test cases executed must be generated.
- Test campaigns with potentially large numbers of test cases will have to be managed, sequenced, and run.

## 4.2 SDAI implementation types

This clause describes the nature of SDAI implementations that are addressed by the test methods specified in this part. SDAI implementations can be of two types - implementations that accept requests encoded in the binding language of the implementation and respond to these requests in the manner required by the standard, and applications that make a series of these requests to achieve a meaningful objective.

- A SDAI implementation encapsulates repositories and presents an interface for the manipulation of these repositories and schema instances. This is the interface which applications would use to interact with SDAI implementations.
- Application programs use the SDAI interface to communicate with a SDAI implementation to perform their tasks. These tasks typically require access to repositories and schema instances. The SDAI implementation provides this access via the interface.

---

<sup>2</sup>This needs to be described in more detail.

This part of ISO 10303 presents test methods for the testing of implementations of the former kind. Test methods for applications that access SDAI implementations are not presented in this part.

### **4.3 Testing architecture**

The architecture assumed by the test methods for SDAI implementations is a simple *client-server*<sup>3</sup> relationship between the SDAI implementation (IUT) and the test engine. The test application, which is a part of the test engine, plays the role of an application by making SDAI operation requests to the IUT. The IUT returns output back to the test application. A simplified description is presented in Figure 1.

The test application processes the outputs and, in turn, communicates appropriate values to the test engine for recording.

The test application uses test data as appropriate to execute its test cases.

---

<sup>3</sup>The use of the term *client-server* has been viewed by some members of WG6 and 7 as carrying too much meaning, and thereby subject to misinterpretation by readers. It is still here since the editor of this part has not found a sufficiently high-quality substitute.

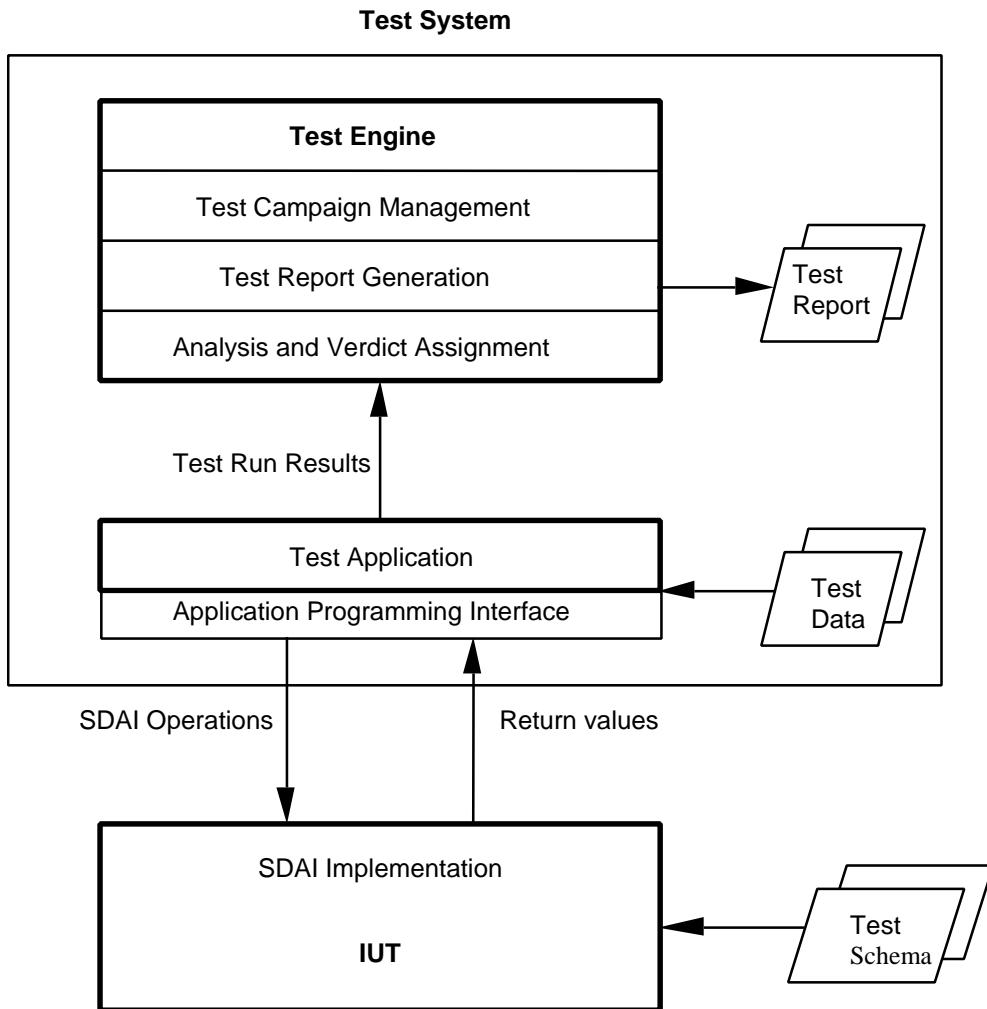

Figure 1 Testing architecture for SDAI implementations

## 5 Testing process

### 5.1 Preparation for testing

PICS and PIXIT proformas are completed by IUT vendors prior to testing. The information in these forms is used to guide test case selection, sequencing, and input data to be used in the execution of the test campaign.

Abstract test cases are built around SDAI operations specified in ISO 10303-22. Since there exists no guaranteed one-to-one relationship between operations in ISO 10303-22 and a particular language binding, executable test cases are developed to logically match these operations so that the executable test cases can be grouped according to implementation level.

## **ISO TC184/SC4/WG11 N137**

Note: This part of ISO 10303 may also need to specify detailed guidelines for developing and documenting abstract test cases.

Executable test cases are built from the abstract test cases using PICS and PIXIT information for an IUT. The sequence of their execution in a test campaign is determined at this stage.

Note: In assembling executable tests for an IUT, of particular importance is information about the IUT's implementation class, whether it is early or late-bound, the application schema it is bound to (if early bound), and the programming language of choice.

For a further description of conformance testing preparations from the perspective of the testing laboratory, see ISO 10303-32.

### **5.2 Test campaign**

A conformance test campaign is a sequenced execution of all required executable test cases (ETCs). The results of this sequenced execution determines conformance.

Modifications to the IUT are not permitted during a test campaign. Modifications to the ETCs or to the sequence of their execution is not permitted during a test campaign, except in the situation where the ETC is determined to be in error.

If an ETC is determined to be in error, a verdict of INCONCLUSIVE shall be assigned to its execution until the error is resolved and the test repeated.

### **5.3 Test conclusion**

A test campaign may terminate for any reason. A normal termination of a test campaign occurs when all its executable tests have been run. A PASS verdict is assigned to a campaign if all the tests of the campaign have returned PASS verdicts and no violation of any ISO 10303 part is detected.

### **5.4 Test report production**

A conformance test report is created after a test campaign terminates. As a minimum, this report shall contain information identifying the IUT and the capability that is being tested (late/early binding, SDAI implementation class(es) supported, binding language, AP or application schema information, etc.) and a detailed reports and verdicts on all the executable tests in the campaign including a list of those not executed, if any. Any relevant information on the testing environment will be included as well.

## **6 Test method - early-bound implementation**

An early bound SDAI implementation provides an interface specific to the application schema to which it is bound at compile-time. The test application that will have to be written to test an early bound IUT will therefore depend on this application schema.

The set of early bound functions that need to be tested can be classified in two broad groups: those that are schema-specific and those that are schema-independent.

The schema-independent functions can be tested in a uniform manner regardless of the application

schema that is bound to the IUT. Test cases for the schema-specific functions will have to be developed for each application schema that may be early-bound to an IUT. The testing of schema-specific functions will typically require the use of schema-independent functions. Therefore, an efficient and realistic approach to testing would combine the two rather than test them in separate groups.

Note: Typically for an AP, a large number of schema-specific functions will be generated. WG11 will have to take a decision on whether it is necessary to exercise all these functions, or whether, an appropriately selected subset would suffice.

## 7 Test method - late-bound implementation

A late bound SDAI implementation provides a single generic interface, which may be used with any application schema. Nothing more can be said about the implementation since the implementor has complete freedom in adopting an implementation approach. In an extreme case, a late-bound implementation for a particular application schema could be early-bound, with an interface that mimics the interface of a late-bound implementation.

Therefore, the testing of late-bound implementations would also have to be in the context of a specific application schema, usually an AP. Testing would progress in a manner similar to the testing of early-bound implementations<sup>4</sup>.

## 8 Test Application

Test purposes are statements of requirements that are used in the development of abstract test cases. They are derived from two sources: ISO 10303-22, and the application schema(s) for which the implementation is being tested. For ISO 10303-22, they are derived from ISO 10303-22, clause 10 (operation test purposes) and clause 12 (state model test purposes). Each test case satisfies one or more test purposes.

Operation test purposes, derived from clause 10 of ISO 10303-22, specify the execution of operations in normal and under error conditions. For this purpose the SDAI operations are mapped into functions and procedures of the SDAI\_test\_operation\_schema, see Annex A. In addition to the parameters specified in ISO 10303-22:10 parameters for the error code and error base are added. The Test Application shall implement this test-functions and procedures for the particular implementation and binding in such a way that the corresponding SDAI operation is invoked and the specified error is checked.

Operation test purposes do not contain the error indicators SS\_NAVL, SY\_ERR, and TR\_EAB (see ISO 10303-22, clause 11).

### Examples

#### 1 - The test purpose

#### Open session

is an operation test purpose which requires that the operation open session be executed normally.

<sup>4</sup>How would an implementation advertising a general late-binding capability be tested? Would it have to be tested for each application schema they becomes available? Hopefully not!

2 - The test purpose

**Open session** terminating with SS\_OPN.

is an operation test purpose which requires that the operation be executed such that the error indicator SS\_OPN is returned.

3 - Although the error indicator SS\_NAVL is a possible error indicator for this operation,

**Open session** terminating with SS\_NAVL.

is not a valid test purpose.

## 9 Abstract Test Cases

This clause specifies abstract test cases for SDAI implementations. Each abstract test case addresses one or more test purposes from clause 8. All the test purposes and verdict criteria associated with the test case are explicitly referenced in the test case.

Each operation of a test case is specified on a numbered line. Verdiced operations have parenthesized verdict criteria next to them. If an operation needs an input, it is specified on the next line.

```
SCHEMA SDAI_test_cases_schema;
USE SDAI_test_operation_schema;
USE FROM SDAI_session_schema;
USE FROM greek;
```

In the following test cases attributes of the session entities sdai\_session, sdai\_transaction, implementation, sdai\_repository, sdai\_repository\_contents, sdai\_model, sdai\_model\_contents, entity\_extent and schema\_instance will be accessed by usual EXPRESS expressions in read-only mode.

```
(* Testing the SDAI operation open session.
*)
PROCEDURE test_open_session();
  LOCAL
    session1 : sdai_session;
    session2 : sdai_session;
  END_LOCAL;

  (* Ensures that open_session works correctly when SDAI session is closed.
*)
  session1 := open_session(NO_ERROR, ?);

  (* Ensures that open_session reports an SS_OPN error when SDAI session is
open. *)
  session2 := open_session(SS_OPN, session1);

END_PROCEDURE;

(*

## Annex A (normative) **SDAI test operation schema**

(\*  
The test sequences are defined in a kind of pseudo  
EXPRESS code. For this the SDAI operations are translated into  
EXPRESS procedures, assuming that the session entities are together  
with the application schema available.

The express given here uses the  
GENERIC\_ENTITY from the proposed EXPRESS amendment.  
Furthermore we assume that for every defined type  
which is not a select type, there is an implicit  
definition of a function with the same name which returned this type  
and which accept the base type as parameter.  
In the case of a defined type which is a select type then  
all the possible underlying types of this select are accepted.

Not mapped operations:  
-- 10.4.1 Record error  
-- 10.4.2 Start event recording  
-- 10.4.3 Stop event recording  
-- 10.8.1 Add to scope  
-- 10.8.2 Is scope owner  
-- 10.8.3 Get scope  
-- 10.8.4 Remove from scope  
-- 10.8.5 Add to export list  
-- 10.8.6 Remove from export list  
-- 10.8.7 Scoped delete  
-- 10.8.8 Scoped copy  
-- 10.8.9 Validate scope reference restrictions  
-- 10.9.3 Is SDAI subtype of  
-- 10.10.7 Is SDAI kind of  
-- 10.11.18 Validate real precision  
\*)

## **Annex D** (informative) **Issues Log**

Each issue is set out as follows:

**Issue number** these are assigned sequentially

**Issue date** the date given on the written issue or, where this is not given, the date on which the issue was received.

**Author** the author of the issue may be an individual or a committee.

**Status** the current status of the issue. This is categorized as follows:

**Open** this issue has not been resolved by WG6

**Resolved** a resolution to the issue has been agreed by WG6; a brief discussion of the resolution is given together with a reference to the version of the Part document in which the resolution is fully documented.

**Rejected** the issue has been discussed by WG6 but has not been accepted. A brief statement of the reason for rejection of the issue is given.

**Clarification sought** the issue is not understood by WG6; the author has been asked to supply additional information.

**Deferred** the issue has been discussed by WG6 and, while it has been agreed that this issue is valid, it has been agreed that resolution will not be possible until a future version of the Part. A brief statement of the reasons for the deferral are given.

**Other projects** are named (WGn/Pm) if WG6 has found it necessary or expedient to consult with other projects or working groups in resolving, rejecting or deferring an issue.

Note: Where other projects are indicated for an **open** issue, this indicates that WG6 (or, in some cases, the document editor) has identified a requirement to consult with other projects or working groups.

**Issue text** the text of the issue as documented by its author.

**Technical discussion** see comments above regarding the statement of reasons for the acceptance, rejection or deferral of an issue.

## **Issues**

### **Issue 1**

**Date:** 12 June 1995

**Author:** Shantanu Dhar

**Status:** Open, to be resolved, Lothar Klein, 1999/11/07

The Guidelines for the development of abstract test suites address the testing of preprocessors and postprocessors, i.e. only the exchange structure is addressed. The specification, development, and documentation of abstract test cases and suites has to be addressed. Part 35 or a companion document would have to address this.

**Technical Discussion:** Part 35 will contain all abstract test cases as EXPRESS procedures in the SDAI\_test\_cases\_schema. In addition to this the corresponding part 21 input and output will be given as comments. It is up to specific implementation and language binding to specify proper test suites. For the complete Java(TM) programming language binding to the SDAI test suites for late and early binding will be given in an informative annex.

### **Issue 2**

**Date:** 12 June 1995

**Author:** Shantanu Dhar

**Status:** Open, to be resolved, Lothar Klein, 1999/11/07

WG 6 and 7 need to resolve the issue of exhaustive testing of early bound implementations. The question is: Is it necessary to exhaustively test every function for the creation, deletion, and modification of every entity type in the application schema? Or does a judiciously chosen representative set of such functions adequately address testing needs.

**Technical Discussion:** This selection is done by specifying the artificial "Greek" test schema. Instances of the specified entities are created, deleted and modified in the given test cases.

### **Issue 3**

**Date:** 12 June 1995

**Author:** Shantanu Dhar

**Status:** Open, to be resolved, Lothar Klein 1999/11/07

ISO 10303-22 specifies error conditions for all operations. Testing will have to check whether an implementation does indeed return the appropriate error values when error conditions are encountered. This implies error test cases would have to be part of SDAI test suites.

**Technical Discussion:** The SDAI operations are mapped into EXPRESS functions and procedures of the SDAI\_test\_operation\_schema with additional parameters for expected error codes and error base. The

given test cases specify which error conditions of the many possible to test.

**Issue 4**

**Date:** 7 November 1999

**Author:** Lothar Klein

**Status:** Open

In the original EXPRESS (ISO 10303-22 + TC1 + TC2) there is no predefined method for type casting simple data type values for named types. Especially for select data types of named data types this is a real problem. The only way to solve this in EXPRESS 1 is to define functions with the proper return type. Part 35 requires a default mechanism in EXPRESS to do such casting for the EXPRESS planned Amendment 1.1. This should consider either the "type\_mark" from EXPRESS 2 (WG11N81) or (better) for every named type declaration defines an implicit function with the same name which returns this type and accept as its parameter the underlying type.

**Technical Discussion:**

## **Index**
